# Why Cephalopods

- Play a vital (sometimes keystone) role in marine ecosystems
- Fisheries importance (20% of global landings)

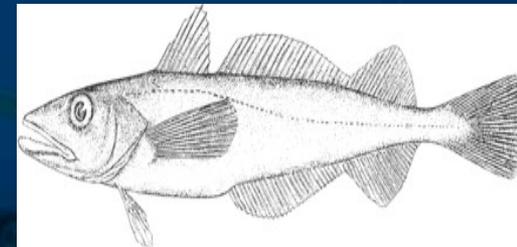

(Clarke 1996; Ruiz-Cooley et al. 2004; Clarke 2005; Ruiz-Cooley et al. 2006)

# Ecology and Life History

- Abundant, fecund and semelparous reproduction with ~1 year lifespan
- Cephalopod physiology and populations directly tied to physical environment (temp, O<sub>2</sub> binding of blood)
- Squid population abundances directly affect those of other taxa

Grey-headed Albatrosses  
*Thalassarche chrysostoma*

Pacific hake  
*Merluccius productus*

# Early Life Sensitivities & Consequences

- Impaired development, size, and survival shown for a variety of species

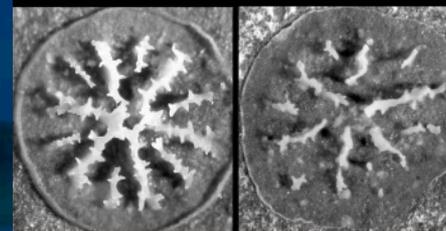

(Kurihara 2008, Ries et al. 2009; Baumann et al 2010)

- Impacts influence recruitment success thus could reduce populations

(Munday et al. 2010)

- Studies have largely focused on marine calcifiers; Impacts to soft-bodied invertebrates is perhaps less understood

- Within cephalopods, much focus on cuttlefish

Anne Cohen, WHOI

David Liittschwager/NGS

(MBL)

(Radtke 1983, O'Dor et al. 1994, Pörtner et al. 2004; Hoegh-Guldberg et al. 2007, Gobler et al. 2014).

# *D. Pealeii* - Coastal Squid

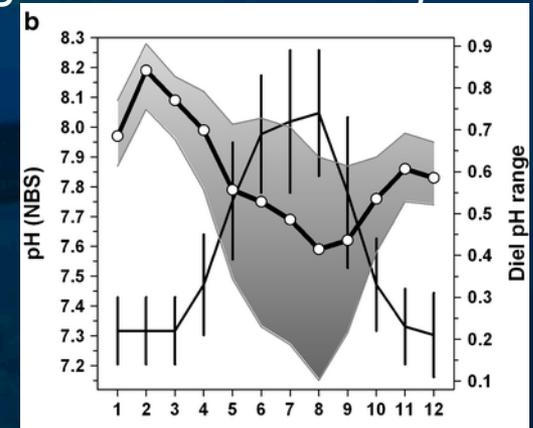

- Habitat Range: Nova Scotia to Brazil
- Adults pelagic – Benthic eggs
- Habitat: Dynamic, productive, coastal ecosystem
  - Bridge between better-addressed estuaries and open ocean

*Breeding squid and egg mat*

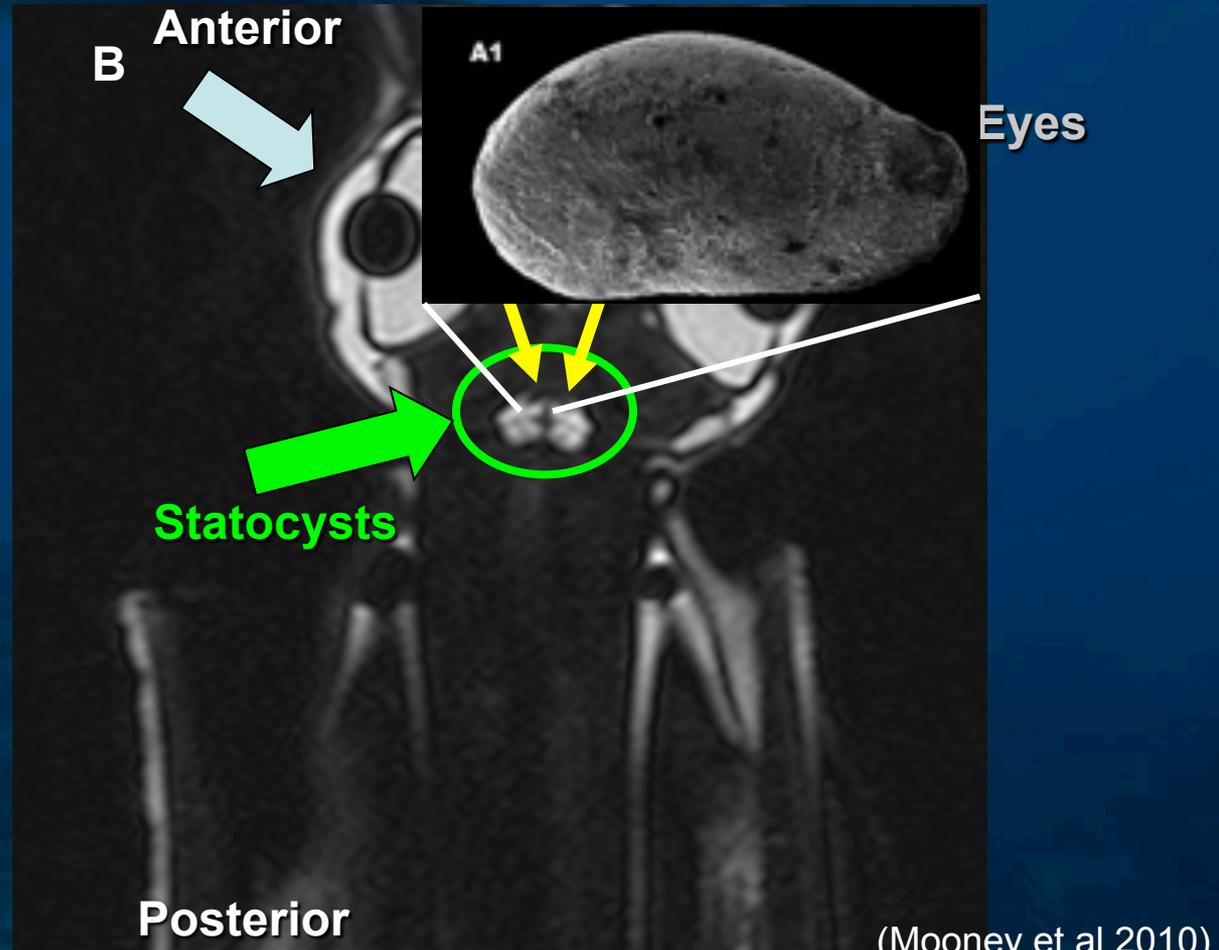

*Long Island Salt Marsh pH range*

(Baumann et al 2014)

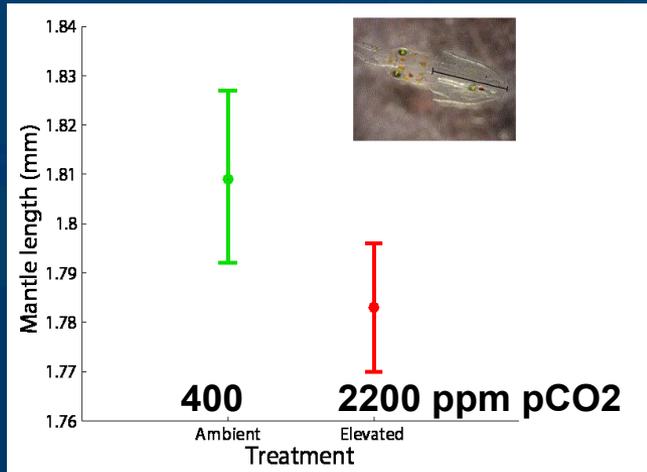

# Squid Statoliths

- Aragonite statoliths (inside the statocyst) = squid inner ear (vital for balance, swimming, hearing, orientation)

# Our Initial Experiments

## Development

( $F_{1,292} = 9.241, p, 0.003$ )

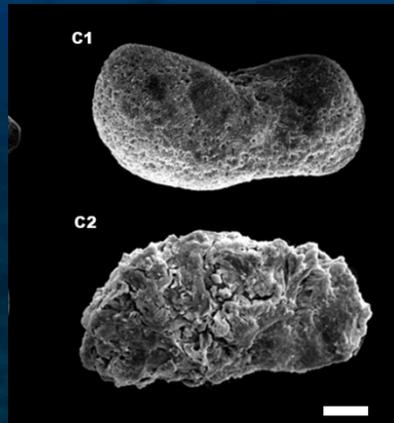

High CO<sub>2</sub> treated animals:

- Hatched smaller
- Hatched later

## Statoliths

400 Ambient

2200 ppm pCO<sub>2</sub>

- Significantly reduced surface area
- Greater porosity

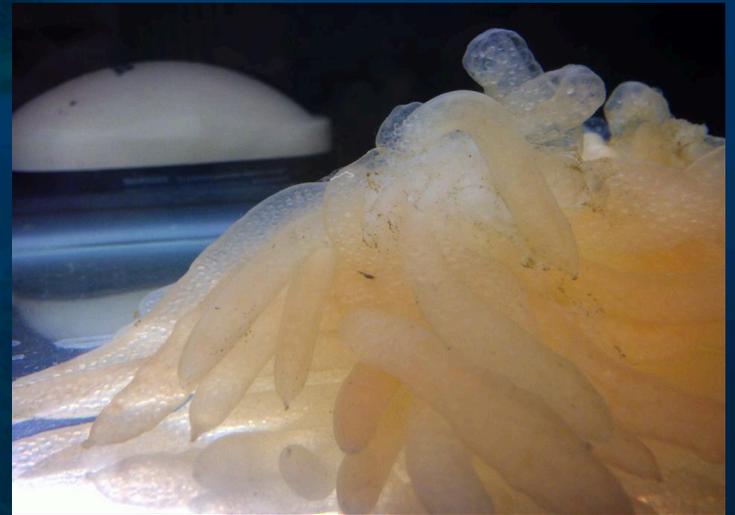

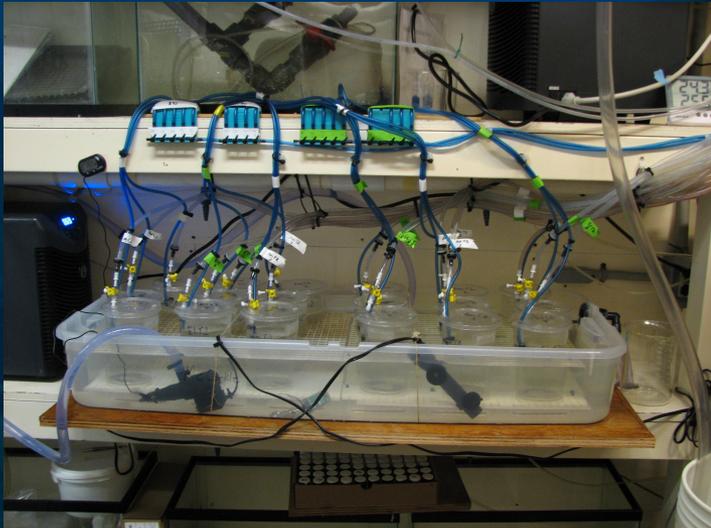

( $F_{1,55} = 70.722, p, 0.001$ )

(Kaplan, Mooney, McCorkle, Cohen, 2013)

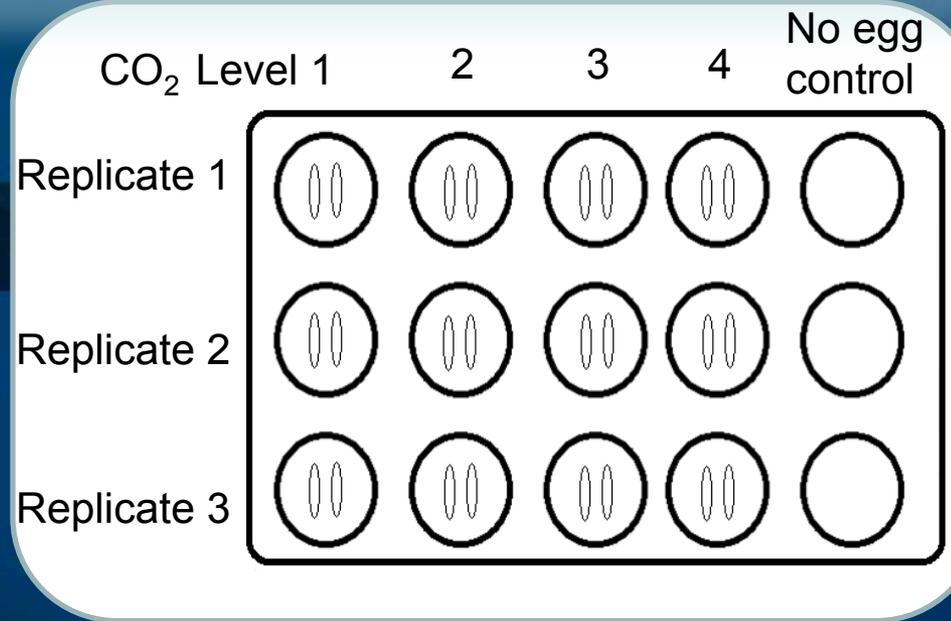

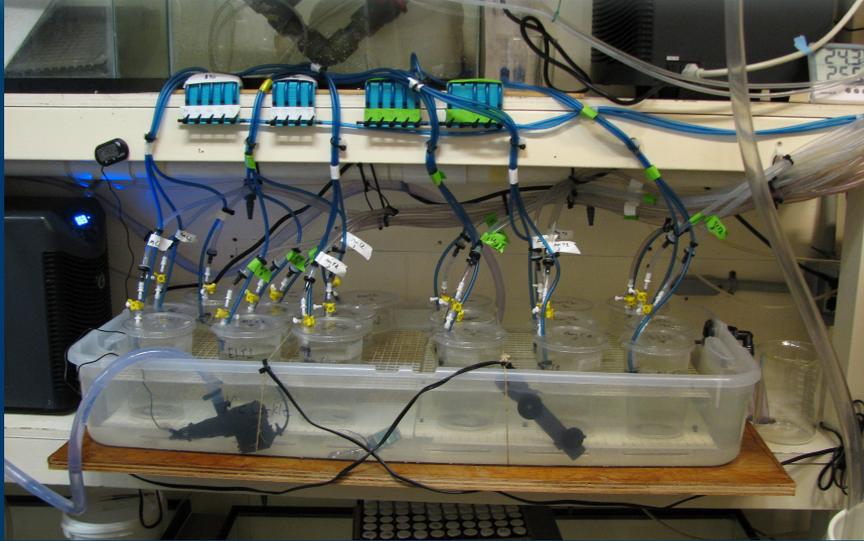

# Goals of these studies

- 1) Quantify the dose-dependent effects of a high- $\text{CO}_2$  environment on squid
  - Where is the 'threshold'? Seasonal (cohort) or annual differences?
- 2) Address mechanisms of changes metabolism ( $\text{O}_2$  consumption and energy reserves)
- 3) Examine consequences of OA impacts: survival and swimming capabilities
  - Velocity, distance, orientation...

# Methods

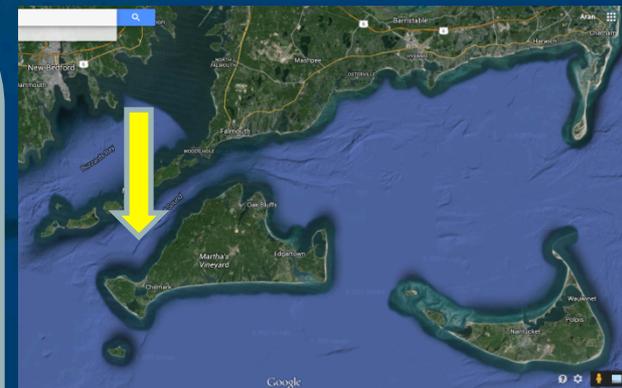

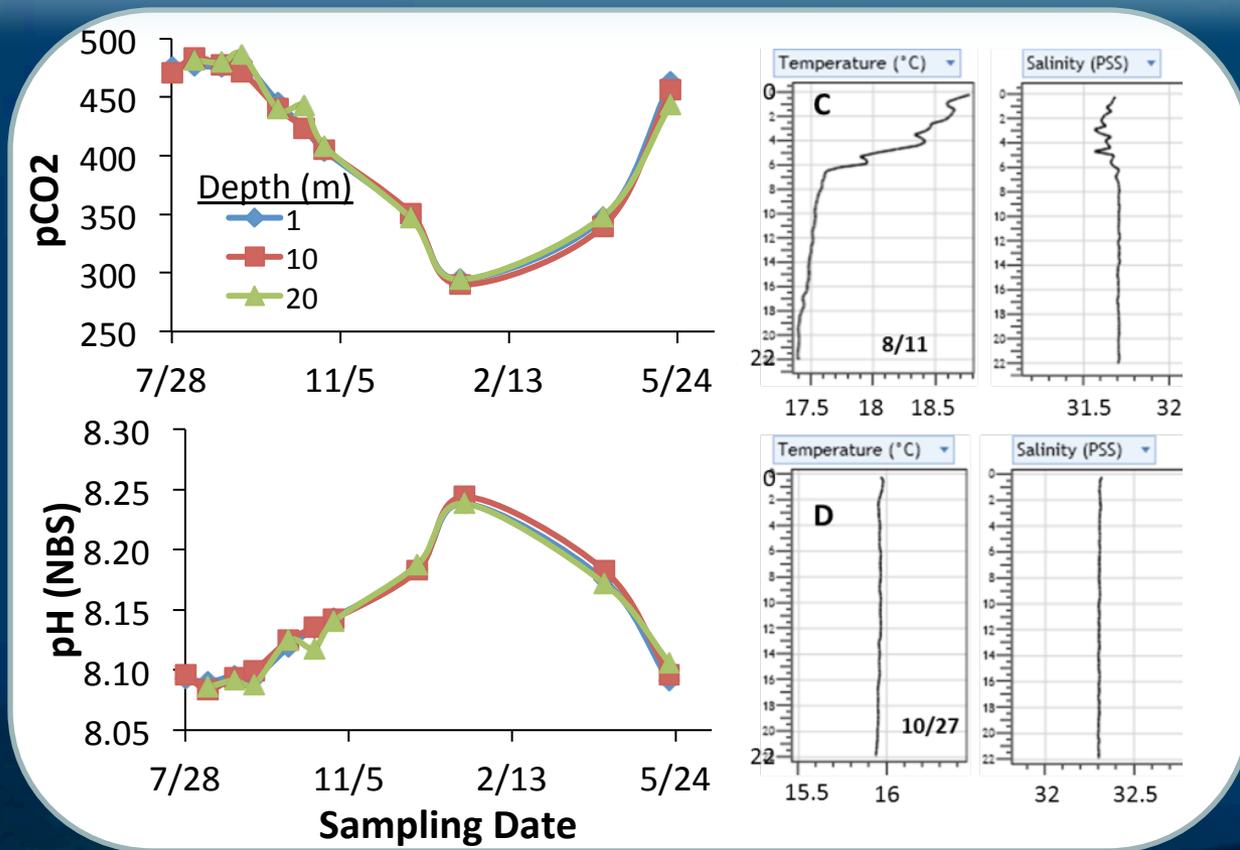

# Methods

- 2+ years, 4-5 trials per season (May-Sept\*)
- Each container bubbled with gas, 4 levels per trial repeating 400 and 2200 as controls
- 3772 animals process for mantle lengths alone
- CO<sub>2</sub> conc measured weekly
- pH measured every 2<sup>nd</sup> day (meter) and weekly (spectrophotometer)
- Salinity measured every 2<sup>nd</sup> day (refractometer and weekly (autosal))
- TA measured with salinity (titration)

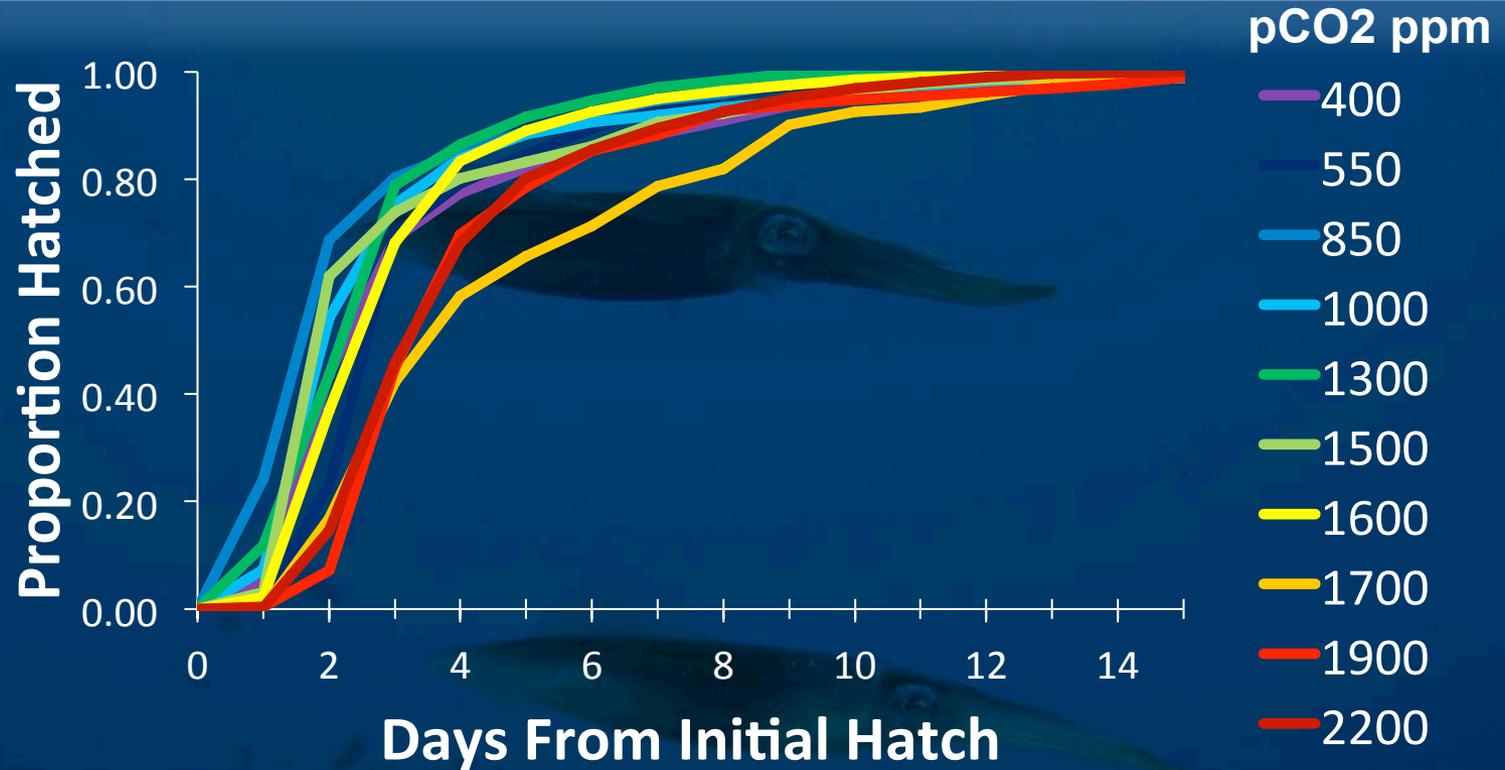

# pH and pCO<sub>2</sub> in squid egg sites

- Bottles and CTD during squid hauls
- Monthly (or more): 28 July 2014 – today
- Currently: 2 week intensive (diel) sampling

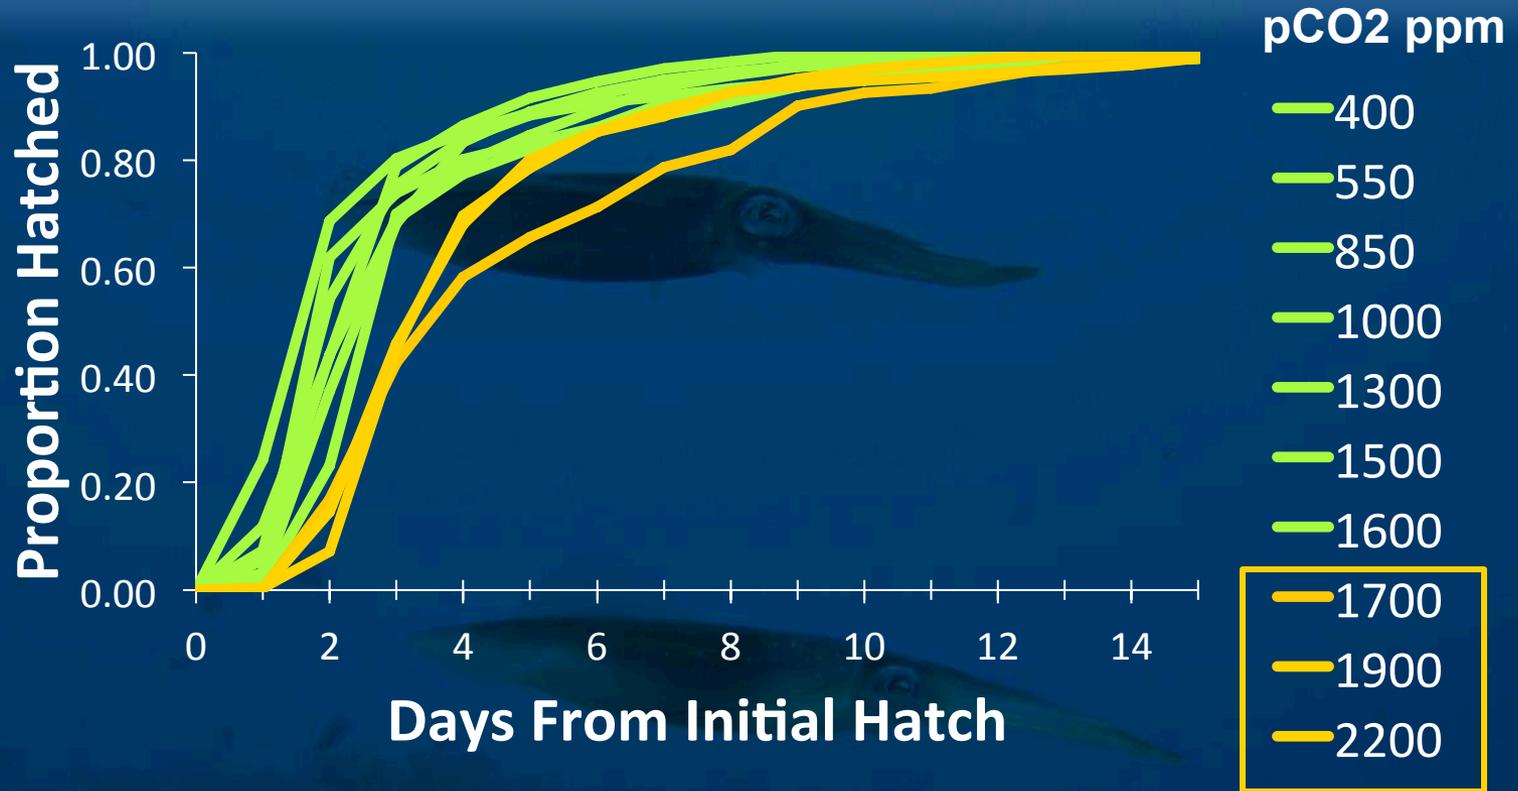

- pCO<sub>2</sub>, pH, and profiles of temp and salinity  
Total depth, 23-25 m
- Water column (1, 10, 20 m depth) generally consistent (but benthos not measured)

# Hatching Delays

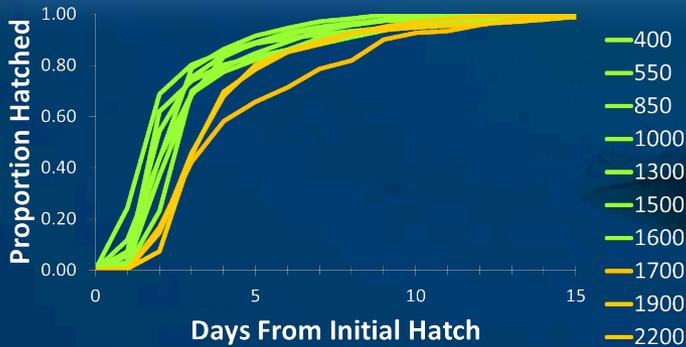

A delay in hatching time of about 1 day occurs in all CO<sub>2</sub> levels above 1600ppm.

# Hatching Delays

- A delay in hatching time of about 1 day occurs in all CO<sub>2</sub> levels above 1600ppm
- Development appears slowed

# Survival

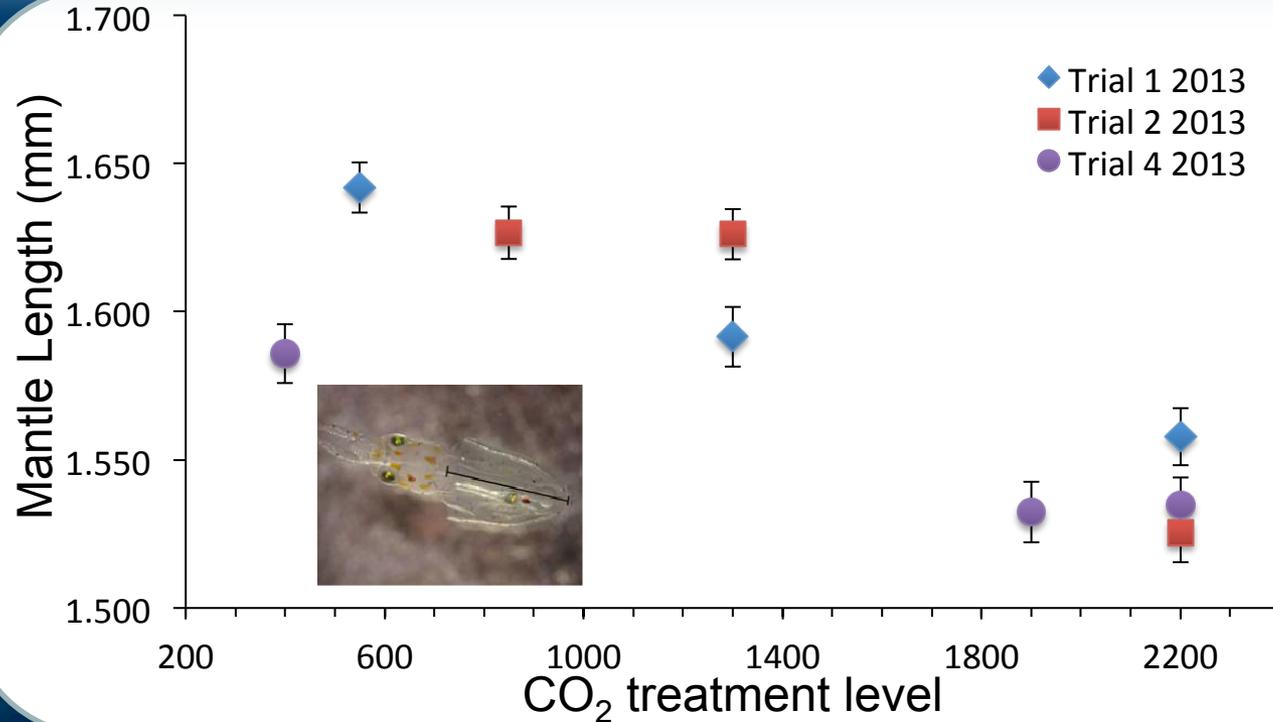

Ambient  
(400 ppm CO<sub>2</sub>)

Elevated (2200)

| Treatment (ppm CO <sub>2</sub> ) | Embryos Survived to Hatching (%) |
|----------------------------------|----------------------------------|
| 400                              | 96.2                             |
| 550                              | 87.4                             |
| 850                              | 93.6                             |
| 1300                             | 95.5                             |
| 1500                             | 98.4                             |
| 1700                             | 94.2                             |
| 1900                             | 93.4                             |
| 2200                             | 94.7                             |

- Survival does not appear impacted

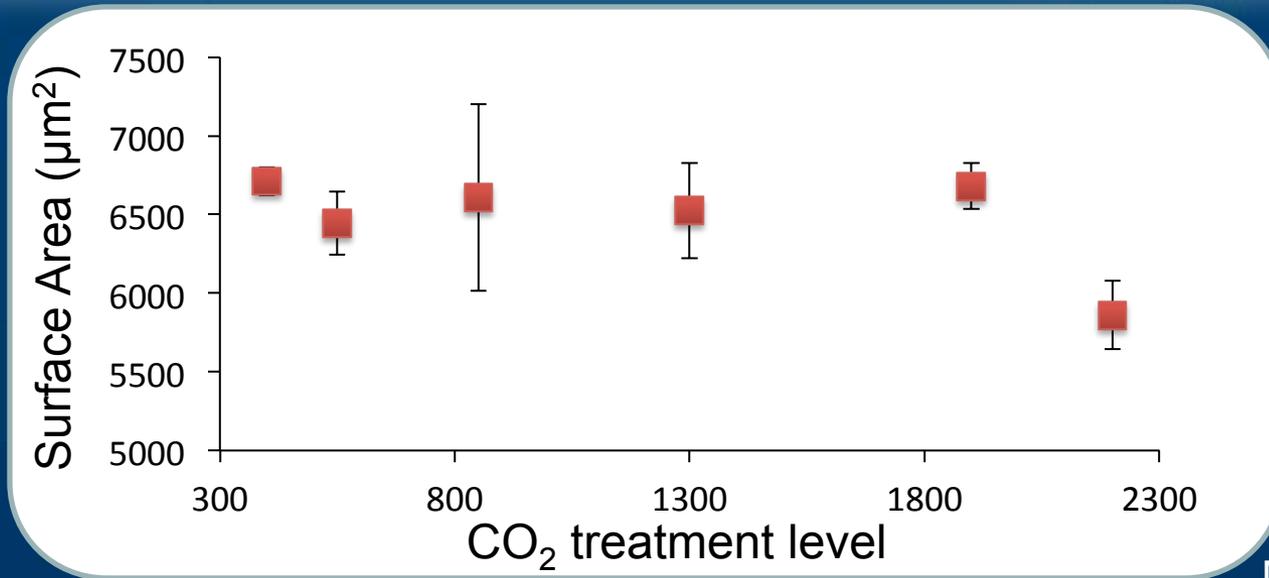

# Mantle Length Changes

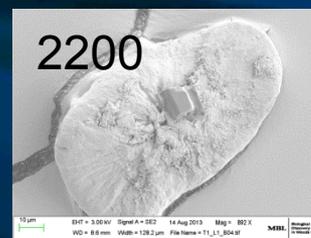

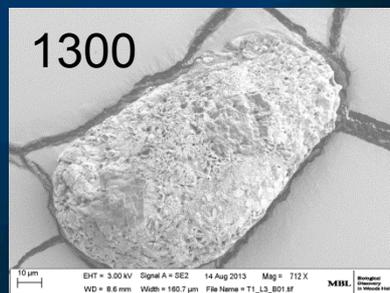

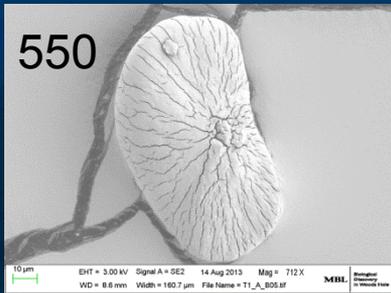

Mean  $\pm$  SE  
K-W  $p < 0.001$

- A ~6% decrease in dorsal mantle length, a metric of somatic growth, from 400 to 2200
- Effect near 1600-1800...

# Statolith Surface Area (2013 data)

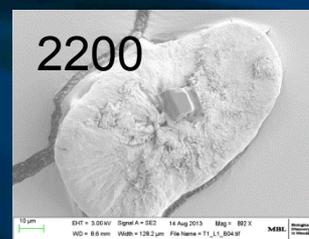

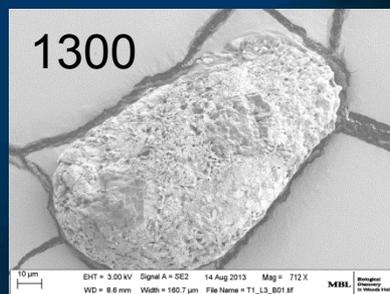

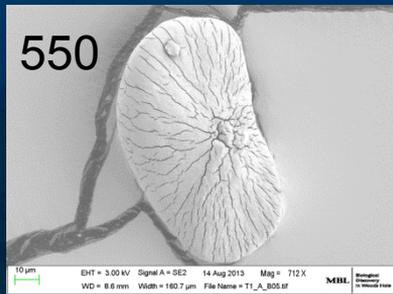

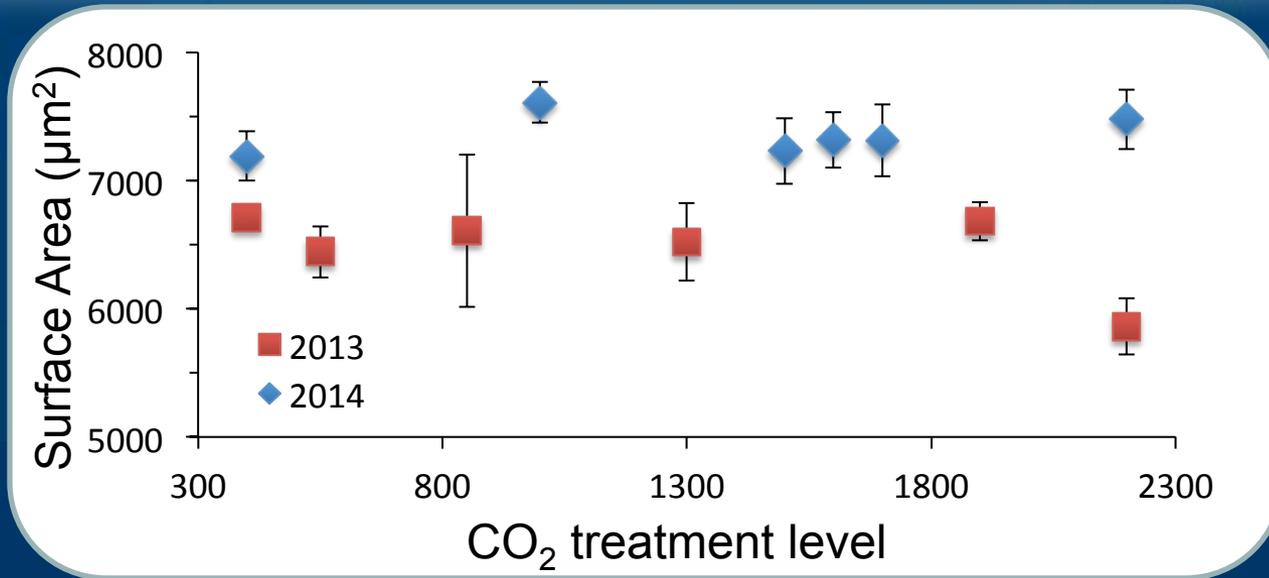

Mean  $\pm$  SE  
K-W  $p < 0.0001$

SEM of statoliths from one trial; (photos to scale)

- Reduction in statolith size is seen in CO<sub>2</sub> exposures at highest levels

# Statolith Surface Area (2013-2014)

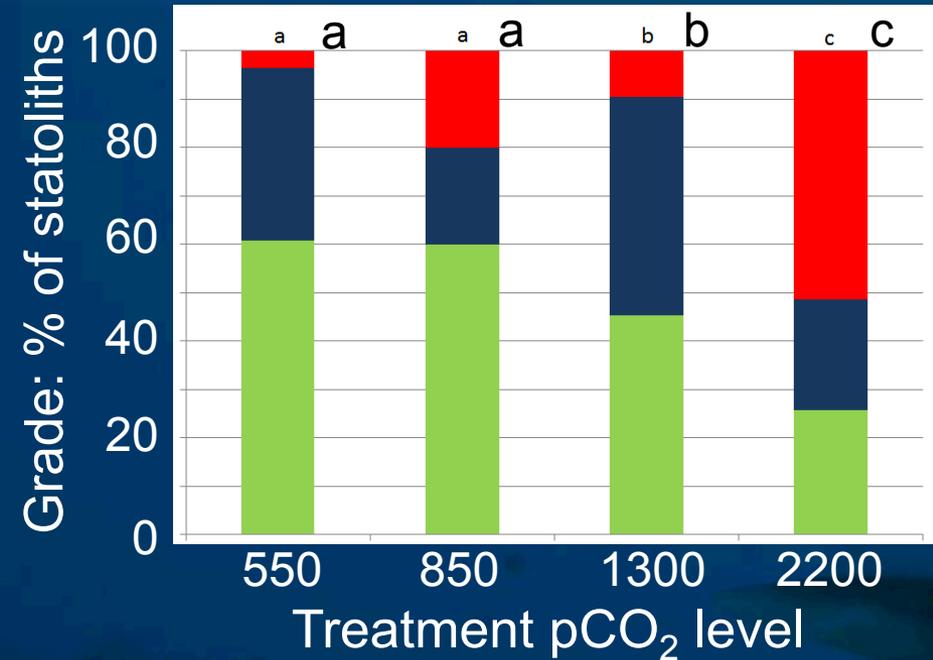

SEM of statoliths from one trial; (photos to scale).

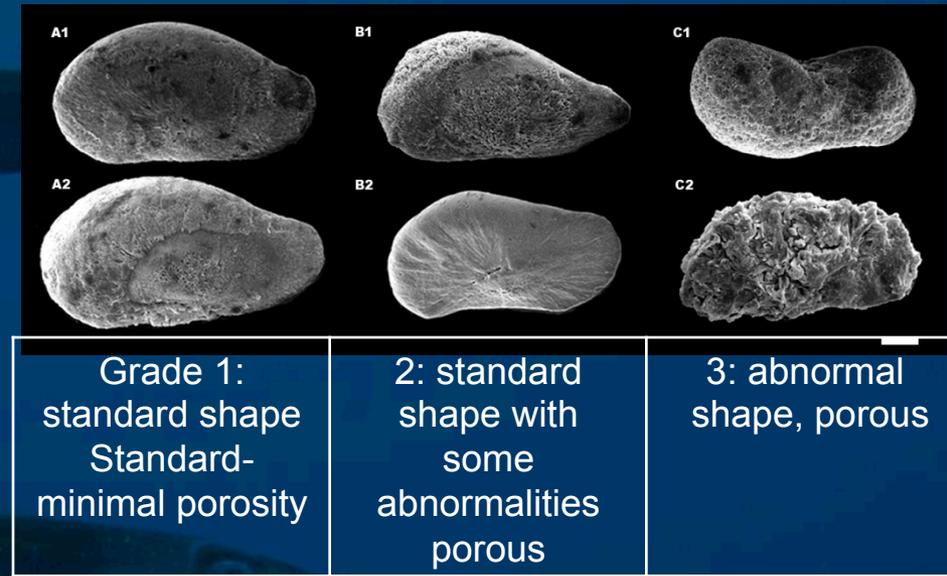

Mean ± SE  
2013: K-W  $p < 0.0001$   
2014: K-W  $p > 0.05$

- Trend does not hold with 2014 data
- (so only 2 of 3 years show differences)

# Statolith Changes

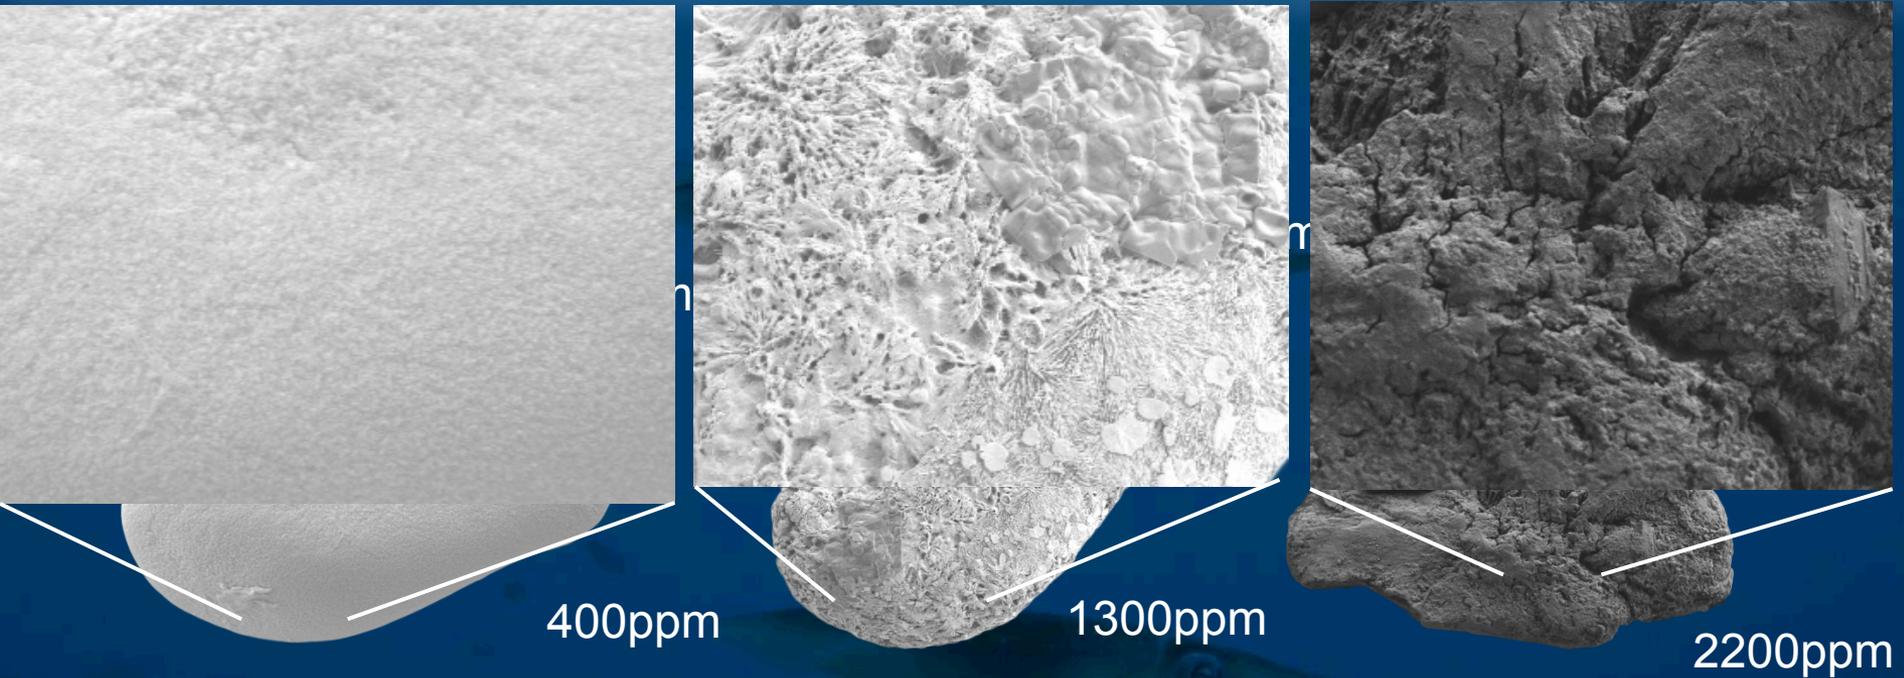

## Statolith porosity grades

- Statoliths were graded based on size, structure, and porosity
- Changes occurred linearly with increase pCO<sub>2</sub> levels

# Statolith Changes

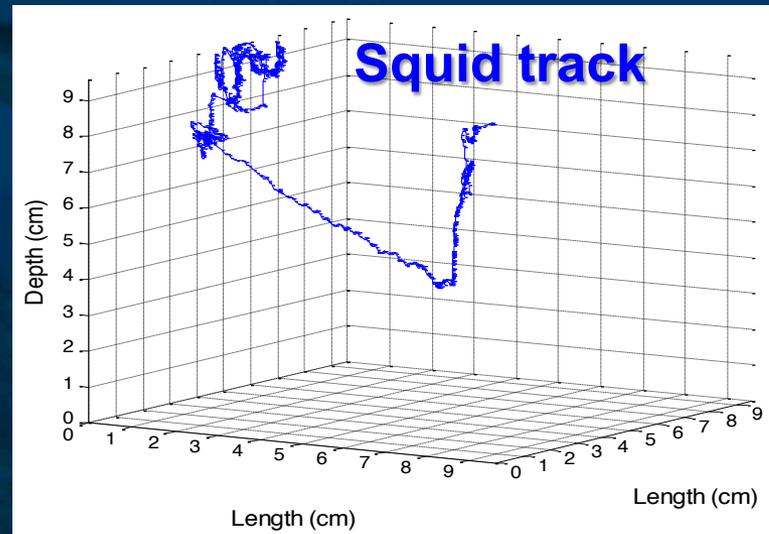

- Aragonite crystals and statolith structure seems to be substantially disorganized with increasing CO<sub>2</sub> levels

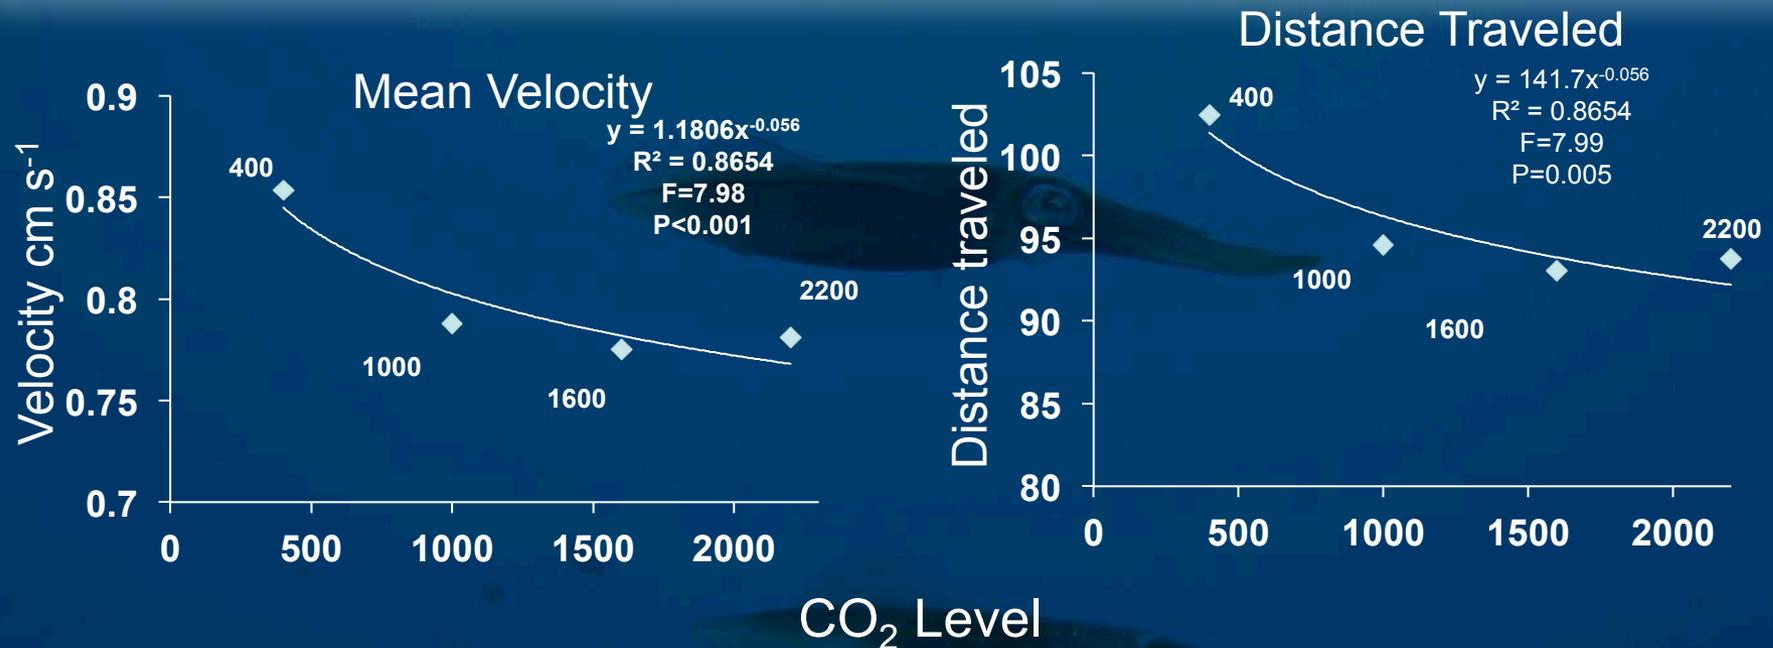

# Swimming behavior

- Swimming behavior tracked with overhead and front HD video
- MatLab track reconstructed in 3D for 2 min (after 30 sec acclimation)
  - Velocity, distance, ethology (swim vs. rest), turn rates, location in chamber

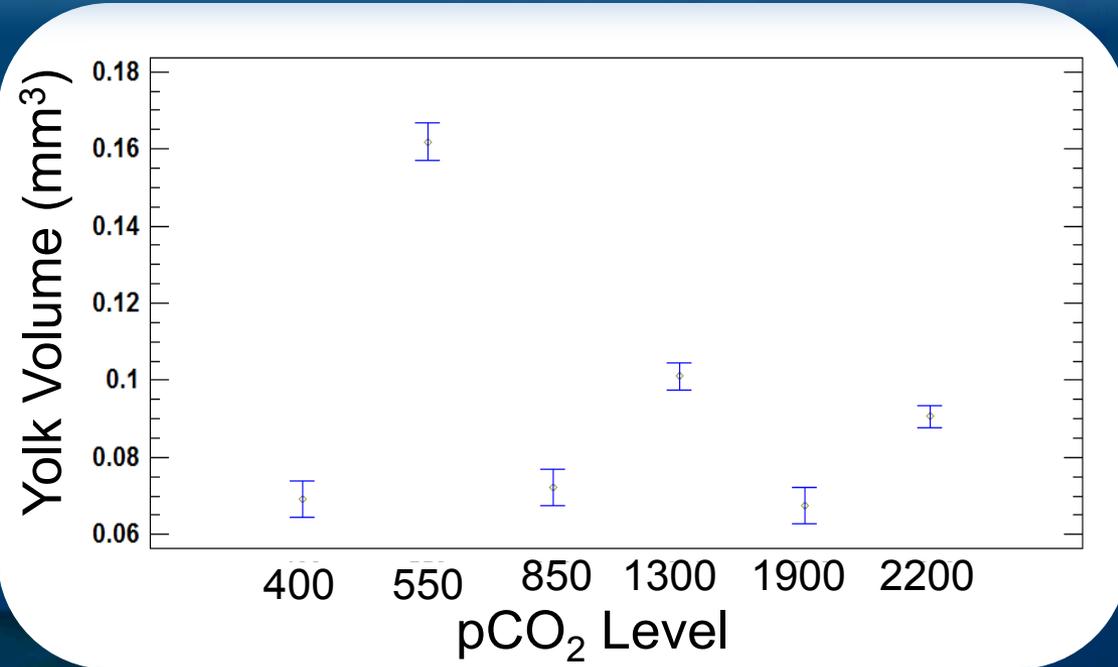

# Swimming behavior

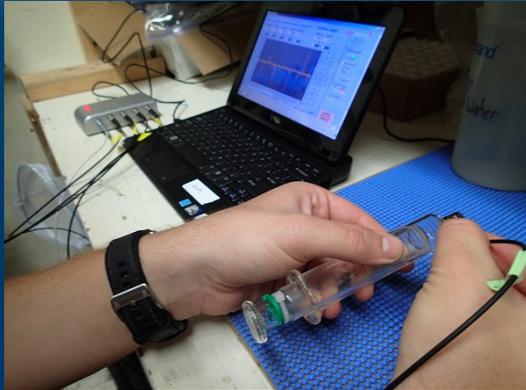

- Decrease in velocity and distance traveled
  - But variance was high and medians were not significantly different
- Sensory experiment (directed swim)

# Metabolic Changes: Yolk sac consumption

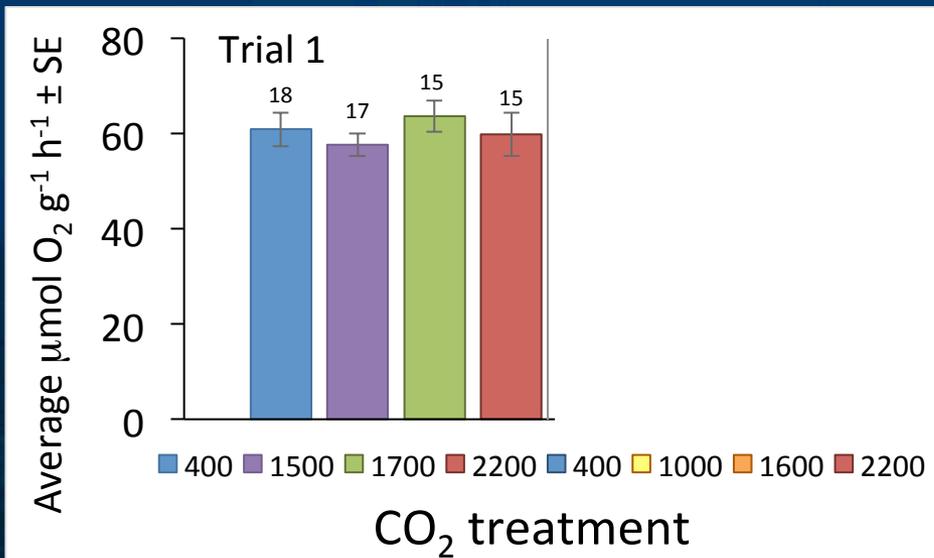

- No significant difference between yolk sac volume and CO<sub>2</sub> exposure
- Animals may not be consuming more energy

# Metabolic Changes: Respirometry

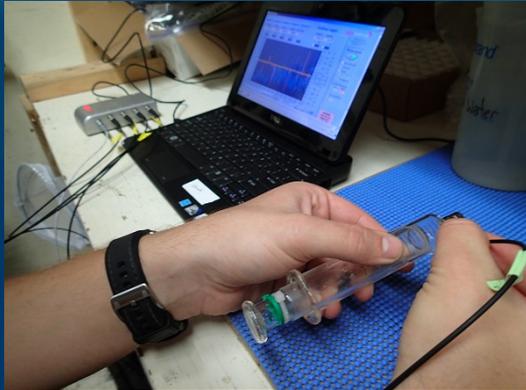

- Hatchlings from each treatment → gas-tight glass respiration chambers with seawater of that treatment level
- Oxygen concentration measured using a FireSting fiberoptic oxygen meter with optical sensor (3-5 hr record, >70% O<sub>2</sub>)

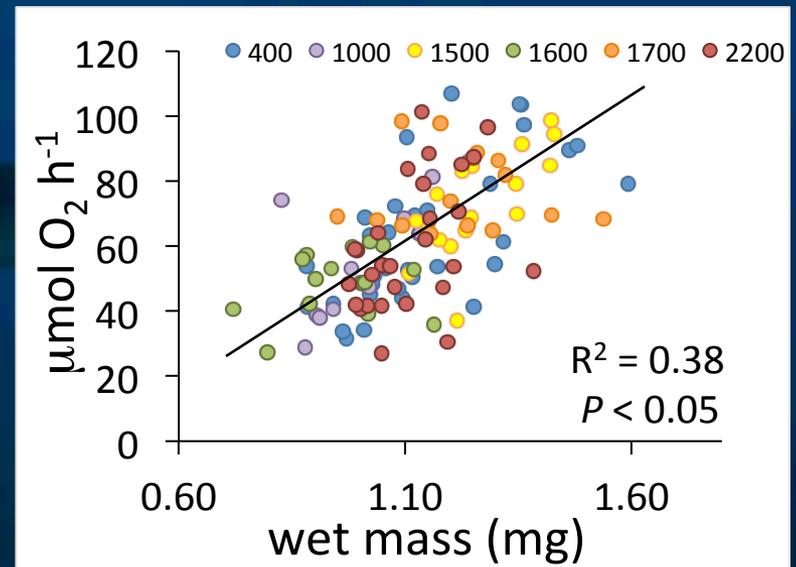

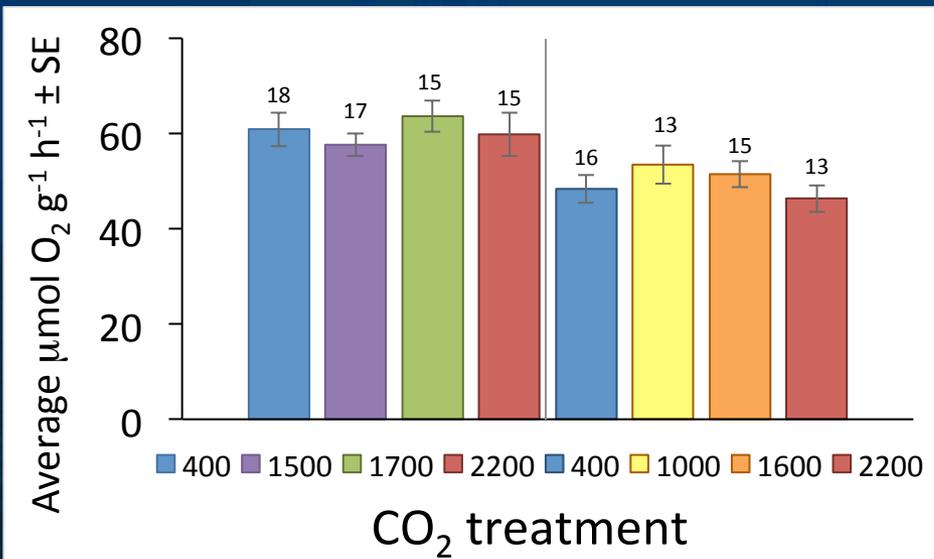

With former WHOI PD: Amy Maas

- No diff. in oxygen consump vs. CO<sub>2</sub> treatment  
(No effect:  $F_{5,114} = 0.737$ ,  $p = 0.597$ )
- Diff based on Trail  
(Effect:  $F_{1,113} = 12.185$ ,  $p = 0.001$ )

# Metabolic Changes?

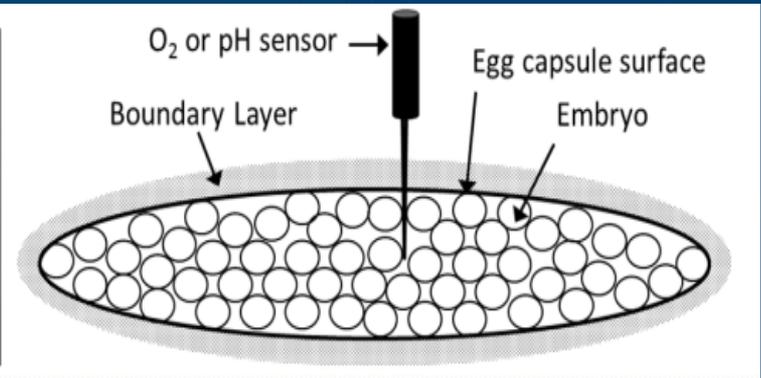

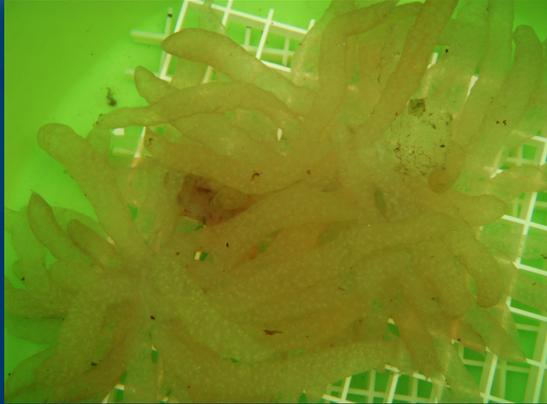

- Effect of mass of the individuals, not CO<sub>2</sub>

( $F_{1,114} = 38.492, p < 0.001$ )

# Profiling egg capsule and boundary layer

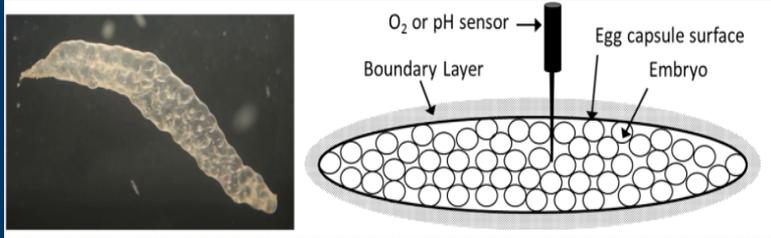

- Oxygen and pH profiles of ambient capsules measured using a FireStingO<sub>2</sub> optical O<sub>2</sub> sensor and liquid ion exchange (LIX) pH sensors

(Gieseke & de Beer 2004)

- Profiled through the water, to a 'boundary layer' at the capsule surface into the capsule center
- Ha: Respiration and capsule membrane will influence local O<sub>2</sub> and pH

# Profiling egg capsule and boundary layer

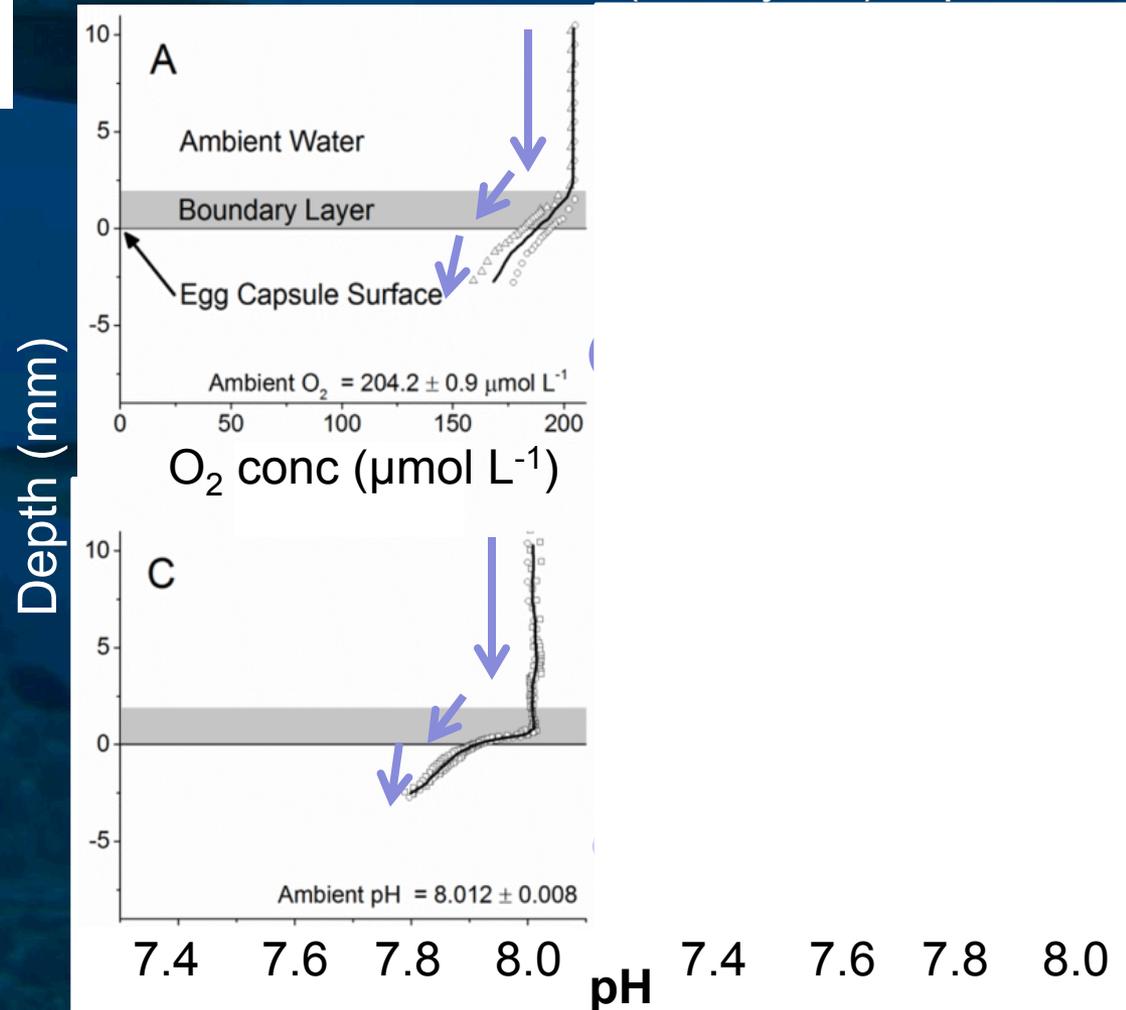

- Near term capsules reached 7.34 pH;
- Capsule O<sub>2</sub> approach zero (1.9)  $\mu\text{mol L}^{-1}$
- Below conc. of Atlantic OMZs
- Below the 50% (7.6) O<sub>2</sub> blood affinity in adult squid...

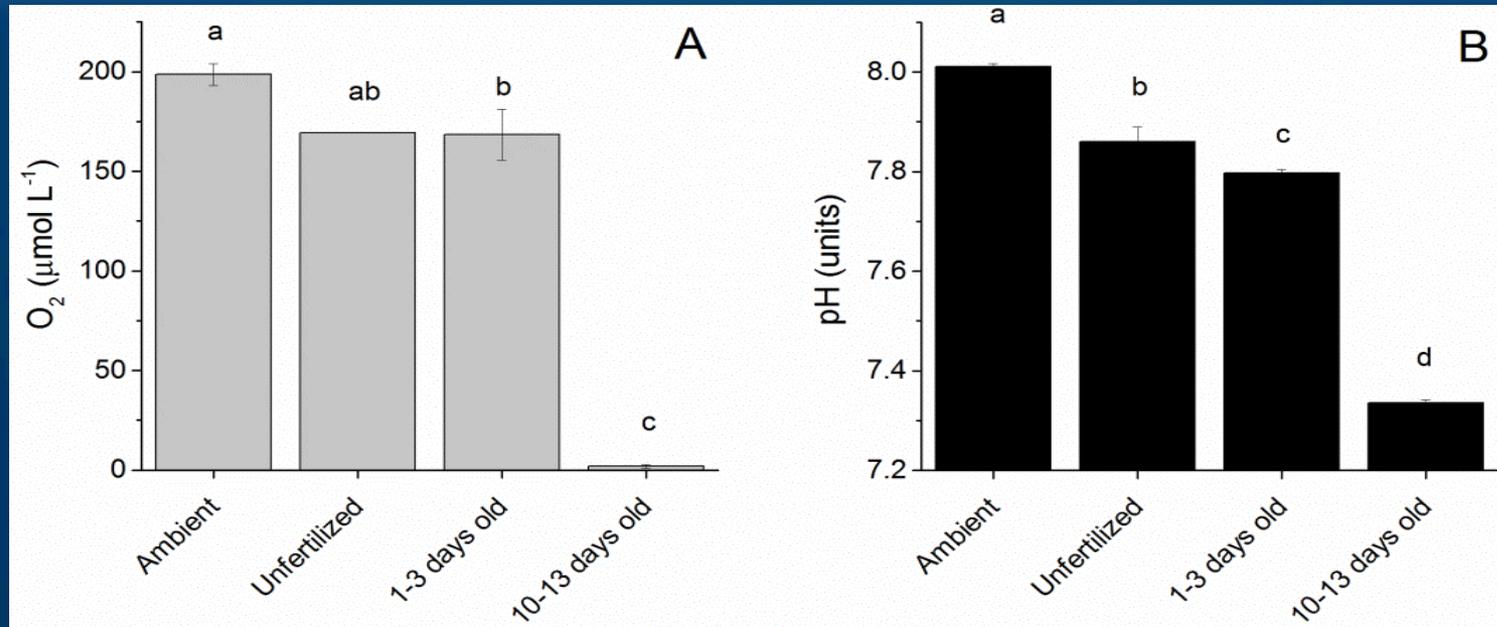

(Long et al submitted)

Newly laid  
(1-3 day old) capsules

Near-full-term (almost hatched)  
(13 day old) capsules

# Profiling egg capsule and boundary layer

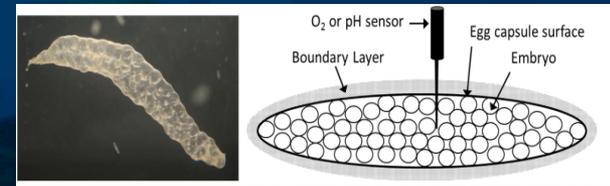

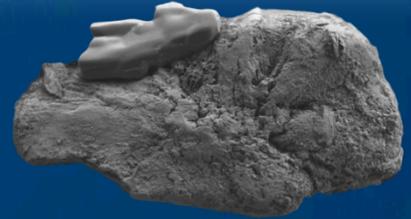

[O<sub>2</sub> ( $p < 0.0001$ ) and pH ( $p < 0.0001$ ); letters indicate differences between groups (using Tukey post-tests)]

- O<sub>2</sub> concentrations (A) and pH (B) dropped significantly from ambient water by capsule age
- Near limit of stress (in capsule)? Increased resilience once hatched?
- Hatching cue?

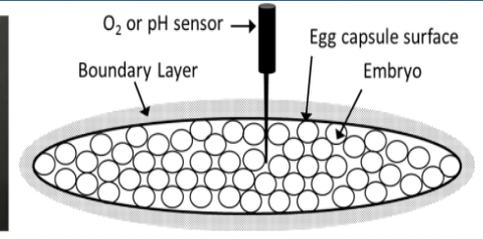

# Summary

- Effects seen but variation by year (and cohort?)
- Development differences not seen in energy expenditures
- Capsules 'naturally' face low pH and low O<sub>2</sub>
- Suggests some resiliency to CO<sub>2</sub> conditions (and much to understand)

# Upcoming Work

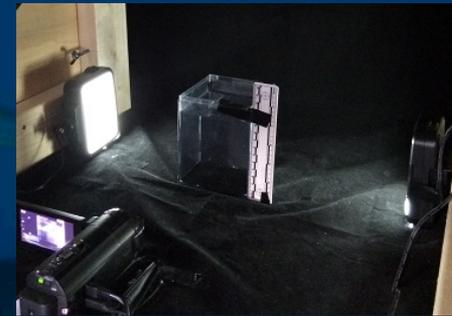

- Egg capsules in an acidified environment and within flow

- Cohort differences (across the summer) and parental contribution

- Statolith composition changes and sensory behavior

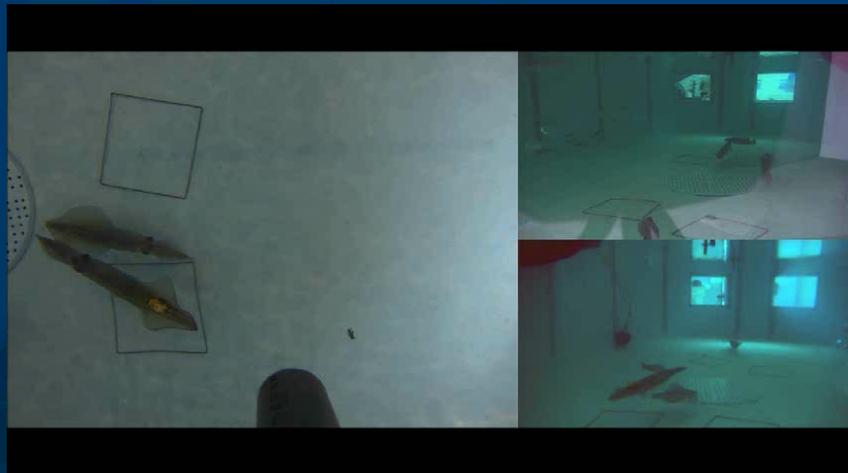

- Natural environment at eggs

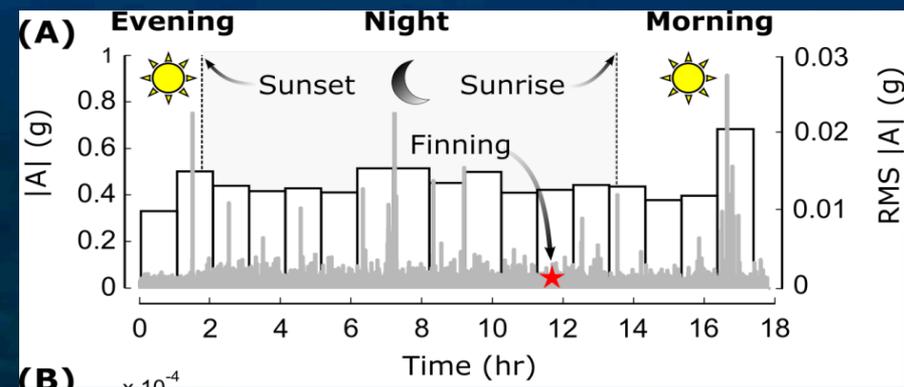

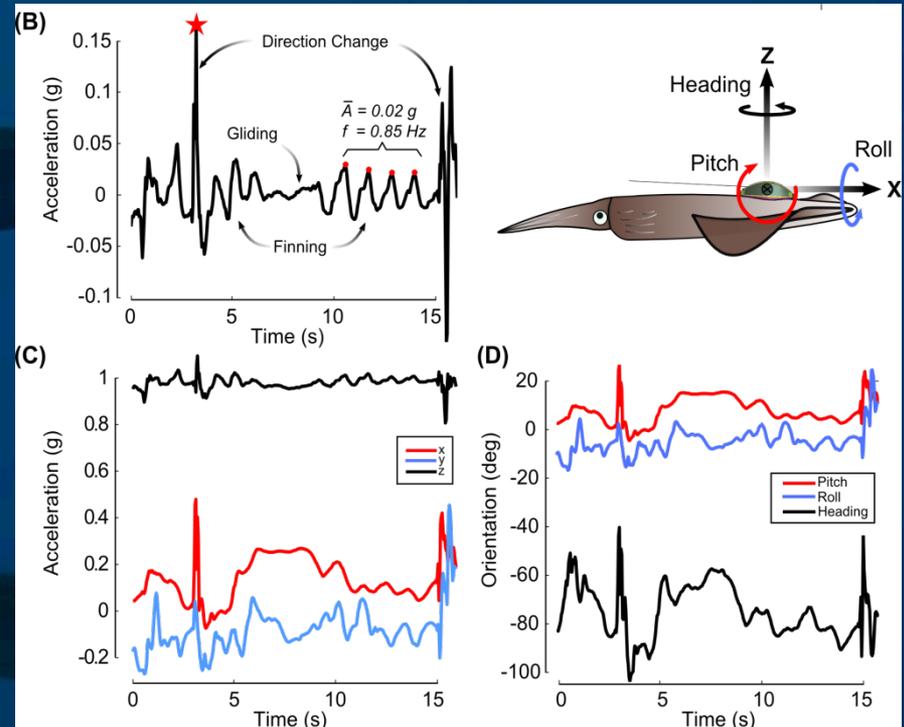

# Upcoming Work

- ITAG: High-sample rate adult vital rates and activity patterns + local environment

- With Aleck Wang – Adding mini-O<sub>2</sub> and salinity sensors

(Mooney et al *in press* Animal Biotelemetry)
